Day #4: Docker > Travis CI > AWS

Q: How do I deploy Docker containers with Kubernetes via Travis CI to AWS or other type of hosting platform?
A: Getting to there.. This is the example of more complex application - multi-container one, close to real-life experience.

Usually, multi-container apps are:

- Complex - with outside dependencies, e.g. DB, helper services like Redis, etc.
- Reusable in the deployment flow - e.g., build a container just once (not like: once on Travis CI while running tests, later on on Travis CI while pushing to AWS Beanstalk)
- With database connected to the container/s
